Beavers Choice Paper Company

Agentic AI Workflow Solution

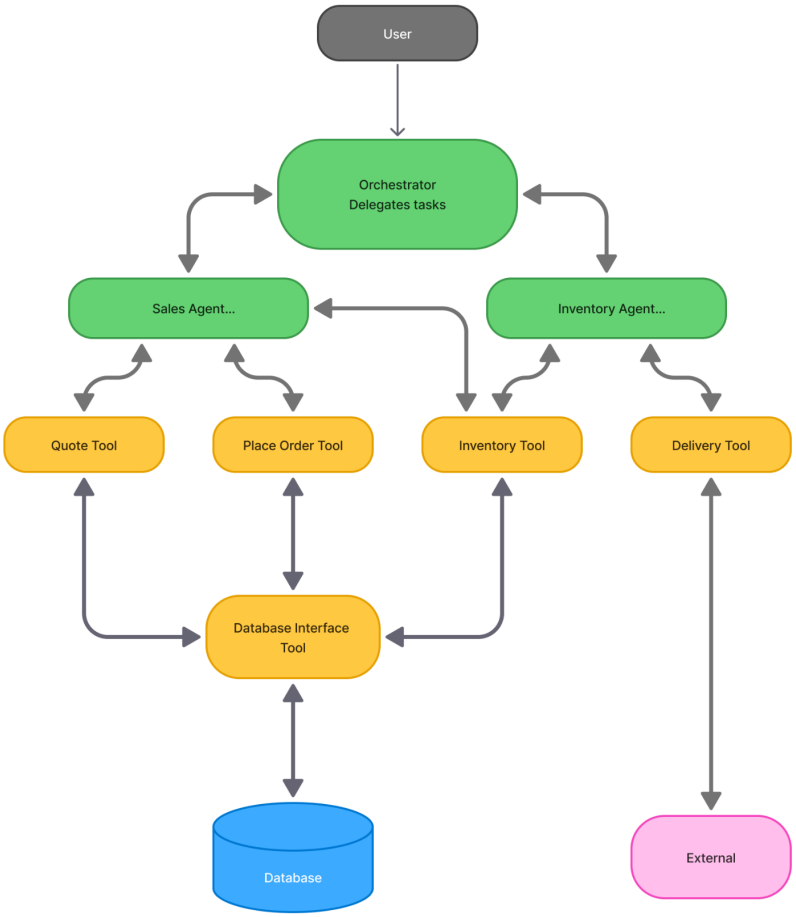
Problem Statement

The Beaver's Choice Paper Company is struggling with managing their paper supplies, responding promptly to customer inquiries, and generating competitive quotes. They're overwhelmed and losing potential sales due to inefficiencies. Your challenge is to design and implement a multi-agent solution, restricted to at most five agents, capable of handling inquiries, checking inventory status, providing accurate quotations, and completing transactions seamlessly. Your solution must ensure responsiveness, accuracy, and reliability in managing requests and maintaining optimal stock levels.

Proposal

Develop a multi-agent system that streamlines operations, enables quick quote generation, accurate inventory tracking, and ultimately drive increased sales.

Multiagent design



Munder Difflin Multi-Agent System Design

Executive Summary The Munder Difflin Multi-Agent System is a sophisticated automation solution designed to modernize the workflows of a paper manufacturing enterprise.

By leveraging a hierarchical multi-agent architecture built on the smolagents framework, the system autonomously handles inventory management, complex quote generation with bulk discounting, and order fulfillment.

The solution ensures data integrity through a centralized SQLite database and provides real-time financial tracking and reporting.

System Architecture

1. **Orchestration Framework** The system utilizes the smolagents library, specifically the CodeAgent and ToolCallingAgent classes. This choice allows for a high degree of flexibility, as the orchestrator can execute Python code to manage the flow between specialized agents, while the agents themselves are restricted to specific tools.

2. **Agent Roles and Responsibilities**
   The system is comprised of three primary agents:

- **Orchestrator** (CodeAgent): Acts as the "Brain" of the operation. It receives natural language requests from customers, decomposes them into logical steps, and delegates tasks to the appropriate specialized agents. It synthesizes the final response for the user.
- **Inventory Agent** (ToolCallingAgent): Specialized in supply chain logistics. It has access to real-time stock levels and supplier lead times.
    - Tools: *inventory_tool, delivery_tool.*
- **Sales Agent** (ToolCallingAgent): Specialized in customer relations and financial transactions. it handles pricing logic and database entry for sales.
    - Tools: *quote_tool, place_order_tool.*

3. Data Infrastructure

- **Database**: A local SQLite database (*munder_difflin.db*) serves as the single source of truth for inventory, historical quotes, and financial transactions.
- **Utility Layer:** A robust set of Python functions (e.g., create_transaction, search_quote_history) abstracts complex SQL operations into simple API calls for the agents.

Design Decisions

The chosen implementation was a **Hierarchical Delegation with a Manager-Worker pattern** was implemented. The Alternative being a flat structure where all agents can talk to each other)

The **Orchestrator** manages the state and sequence, preventing "agent loops" and ensuring that the system follows a logical business process: Stock Check → Quote → Order Placement.

Tool-Centric Agents do not have direct access to the database. Instead, they interact with the data through dedicate tools. This ensures that the LLM cannot execute arbitrary SQL, maintaining data security and structural integrity.

Intelligence-Driven Quoting The quote_tool was designed to be "context-aware." It doesn't just calculate a price; it performs a vector-like search (using keywords) on search_quote_history.

This allows the agent to justify its pricing based on past successful deals, mirroring a real-world sales professional's behavior.

Scalable Discount Logic An example tiered bulk discount strategy was implemented within the *quote_tool*:

- 0-99 units: Base price
- 100-499 units: 5% discount
- 500-999 units: 10% discount
- 1000+ units: 15% discount

NOTE: *This needs to be adjusted to the business requirements for bulk discounts.*

Meeting the Project Requirements

1. Automation of Core Operations
    - Inventory Checks: The inventory_agent automatically flags when stock falls below min_stock_level and provides estimated restock dates.
    - Quote Generation: Quotes are generated dynamically based on real-time unit prices and the bulk discount logic mentioned above.
    - Order Fulfillment: Transactions are recorded automatically in the transactions table upon order placement, updating the company's cash balance and inventory levels.
2. Constraints and Performance
    - Agent Limit: The system uses 3 agents, well within the 5-agent maximum requirement.
    - Communication: All interactions are entirely text-based, allowing for easy integration with chat interfaces or email systems.
    - Financial Integrity: The generate_financial_report function provides a comprehensive view of Cash, Inventory Value, and Total Assets, ensuring the system remains financially accountable.
3. Data Utilization The system successfully integrates historical data from quotes.csv and quote_requests.csv into the runtime environment, allowing the AI to learn from and reference "Munder Difflin" history.

Conclusion The implemented solution provides a robust, scalable, and intelligent multi-agent system capable of handling the complexities of paper sales and logistics. By combining modern LLM orchestration with traditional relational database management, the system offers a reliable bridge between natural language business requests and structured data execution.
